# About This Work...

*Probabilistic Threshold  $k$  Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space.* [3]

B. Yang, H. Lu, and C. S. Jensen.

- Published in year 2010 at the *EDBT* conference.
- **Minimal Indoor Walking Distance**(MIWD) along with algorithms and data structures are proposed for distance computing and storage.
- Effective object indexing structures, also capture the uncertainty of object locations.
- On this foundation, Probabilistic threshold  $k$ NN (PT $k$ NN) query is studied.

# Motivation

- Indoor positioning makes it possible to support interesting queries over large populations of moving objects.[4]
  - shopping mall, airports, office buildings
  - $k$ NN queries over indoor moving objects enables the detection of approaching potential threats at sensitive locations in a subway system
- Existing  $k$ NN techniques in spatial and spatialtemporal databases are inapplicable in indoor spaces.
  - complex entities and topologies
  - indoor positioning techniques differ fundamentally from outdoor GPS, low sampling frequency and accuracy

## Minimal Indoor Walking Distance

**Minimal Indoor Walking Distance**(MIWD) is used as the distance metric in indoor spaces.

## Minimal Indoor Walking Distance

**Minimal Indoor Walking Distance**(MIWD) is used as the distance metric in indoor spaces.

The mapping *Rooms* determines the room of an indoor position:

# Minimal Indoor Walking Distance

**Minimal Indoor Walking Distance**(MIWD) is used as the distance metric in indoor spaces.

The mapping *Rooms* determines the room of an indoor position:

$$Rooms : positions \rightarrow \Sigma_{rooms} \quad (1)$$

# Minimal Indoor Walking Distance

**Minimal Indoor Walking Distance**(MIWD) is used as the distance metric in indoor spaces.

The mapping *Rooms* determines the room of an indoor position:

$$Rooms : positions \rightarrow \Sigma_{rooms} \quad (1)$$

The mapping *Doors* maps a room to the doors that connect the room to an adjacent room:

# Minimal Indoor Walking Distance

**Minimal Indoor Walking Distance**(MIWD) is used as the distance metric in indoor spaces.

The mapping *Rooms* determines the room of an indoor position:

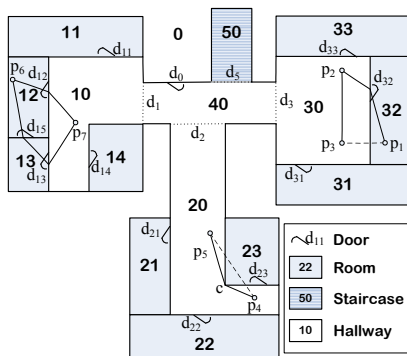

$$Rooms : positions \rightarrow \Sigma_{rooms} \quad (1)$$

The mapping *Doors* maps a room to the doors that connect the room to an adjacent room:

$$Doors : \Sigma_{rooms} \rightarrow 2^{\Sigma_{doors}} \quad (2)$$

## 2.3 Probabilistic Threshold k Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space

## Minimal Indoor Walking Distance

- intra-room obstructed distance, termed as  $d_o$ . E.g.,  
 $d_o(p_2, p_3) = |p_2 p_3|$  and  
 $d_o(p_4, p_5) = |p_4 c| + |c p_5|$ .
- if in different rooms, it should take into account the doors connecting the rooms. E.g.,  
 $d_{MIN}(p_1, p_2) = |p_1 d_{32}| + |d_{17} p_9|$ .
- if there exist several paths, the correct path should be the shortest one. E.g.,  
 $d_{MIN}(p_6, p_7) = |p_6 d_{12}| + |d_{12} p_7|$   
 $\neq |p_6 d_{15}| + |d_{15} d_{13}| + |d_{13} p_7|$ .

## 2.3 Probabilistic Threshold k Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space

## Minimal Indoor Walking Distance

**Doors Graph** is capable of retrieving the connecting doors between two rooms, which is convenient for computing MIWD.

## Doors Graph

- $G_d = \{D, E, l_{weight}\}$
- $D = \Sigma_{doors}$  is the set of the vertices
- $E$ : An edge  $\{d_i, d_j\}$  exists if a room  $rm$  exists in  $\Sigma_{rooms}$  such that  $\{d_i, d_j\} \subseteq Doors(rm)$
- $l_{weight} : E \rightarrow R$  assigns to an edge the obstructed distance between the two doors as  $d_o(d_i, d_j)$

# Minimal Indoor Walking Distance

All **door-to-door shortest path distances** can be computed and recorded in a hash table D2D according to the Doors Graph.

# Minimal Indoor Walking Distance

All **door-to-door shortest path distances** can be computed and recorded in a hash table D2D according to the Doors Graph.

$$\text{D2D} : \{(d_p, d_j)\} \rightarrow R, \quad d_p, d_q \in \Sigma_{\text{doors}}. \quad (3)$$

# Minimal Indoor Walking Distance

All **door-to-door shortest path distances** can be computed and recorded in a hash table D2D according to the Doors Graph.

$$\text{D2D} : \{(d_p, d_j)\} \rightarrow R, \quad d_p, d_q \in \Sigma_{\text{doors}}. \quad (3)$$

Consequently, for two positions  $p$  and  $q$  in different rooms.

# Minimal Indoor Walking Distance

All **door-to-door shortest path distances** can be computed and recorded in a hash table D2D according to the Doors Graph.

$$\text{D2D} : \{(d_p, d_j)\} \rightarrow R, \quad d_p, d_q \in \Sigma_{\text{doors}}. \quad (3)$$

Consequently, for two positions  $p$  and  $q$  in different rooms.

$$d_{\text{MIN}}(d_p, d_q) = d_o(p, d_p) + \text{D2D}(d_p, d_q) + d_o(d_q, q) \quad (4)$$

where  $d_p(d_q)$  ranges over all doors of room  $p(q)$ .

# Minimal Indoor Walking Distance

All **door-to-door shortest path distances** can be computed and recorded in a hash table D2D according to the Doors Graph.

$$D2D : \{(d_p, d_j)\} \rightarrow R, \quad d_p, d_q \in \Sigma_{doors}. \quad (3)$$

Consequently, for two positions  $p$  and  $q$  in different rooms.

$$d_{MIN}(d_p, d_q) = d_o(p, d_p) + D2D(d_p, d_q) + d_o(d_q, q) \quad (4)$$

where  $d_p(d_q)$  ranges over all doors of room  $p(q)$ .

---

**Algorithm 1**  $d_{MIW}(\text{Position } p, \text{Position } q)$ 

---

```

1: if Rooms(p)=Rooms(q) then
2:   minDist  $\leftarrow d_o(p, q)$ ;
3: else
4:   minDist  $\leftarrow +\infty$ 
5: for each door  $d_p$  in Doors(Rooms(p)) do
6:   for each door  $d_q \neq d_p$  in Doors(Rooms(q)) do
7:      $l \leftarrow d_o(p, d_p) + d_o(d_q, q) + D2D(d_p, d_q)$ 
8:     if  $l < \text{minDist}$  then
9:       minDist  $\leftarrow l$ ;
10: return minDist;
```

---

it is possible to adapt this notion of distance to accommodate other semantics. For example, a person might prefer a longer indoor path that passes as few doors as possible.

# Symbolic Indoor Positioning

each device detects and reports the observed objects at a relatively high sampling rate.

A reading  $(deviceID, objectID, t)$  states that object  $objectID$  is detected by device  $objectID$  at time  $t$ .

Only its first and last appearances in a device's range are of interest.

- $flag = ENTER$  indicates that the object is entering the device's activation range
- $flag = LEAVE$  indicates that the object is leaving the device's activation range

## 2.3 Probabilistic Threshold k Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space

## Positioning Devices Deployment Graph [2]

- Two types of positioning devices
  - Partitioning Device – *undirected* (**UP**), e.g.,  $d_{21}$  – *directed* (**DP**), e.g.,  $d_{11}$  and  $d_{11}'$
  - Presence Device – (**PR**)
- Note an indoor space is partitioned into *activation ranges* and *cells*

## Deployment Graph

- $G = \{C, E, \Sigma_{devices}, l_E\}$
- $C$ : the set of cells
- $E$ : the set of edges,  $\{c_i, c_j\}$  where  $c_i, c_j \in C$
- $\Sigma_{devices}$ : a mapping from *deviceID* to activation range and type
- $l_E$  maps an edge to a set of positioning devices, i.e.,  $E \rightarrow 2^{\Sigma_{devices}}$

### 2.3 Probabilistic Threshold k Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space

## Positioning Devices Deployment Graph [2]

- Two types of positioning devices
  - Partitioning Device – *undirected* (**UP**), e.g.,  $d_{21}$  – *directed* (**DP**), e.g.,  $d_{11}$  and  $d_{11}'$
  - Presence Device – (**PR**)
- Note an indoor space is partitioned into *activation ranges* and *cells*

## Deployment Graph

- $G = \{C, E, \Sigma_{devices}, l_E\}$
- $C$ : the set of cells
- $E$ : the set of edges,  $\{c_i, c_j\}$  where  $c_i, c_j \in C$
- $\Sigma_{devices}$ : a mapping from *deviceID* to activation range and type
- $l_E$  maps an edge to a set of positioning devices, i.e.,  $E \rightarrow 2^{\Sigma_{devices}}$

# States of Indoor Moving Objects [2]

- An object is in an **active state** when it is inside the activation range of a positioning device.
- Otherwise the object is in an **inactive state**
- When an object is in the inactive state it is
  - **nondeterministic** if it can be in more than one cell
  - **deterministic** if it is in one specific cell

25:       Add  $O.objectID$  to  $CDHT[c]$ ;

```

---

- ① Line 1: reset  $IDSet$
- ② Lines 2–12:  $O.flag$  is ENTER so check the object's previous state. Remove  $O$  from the corresponding table according its previous state
- ③ Lines 13–14: add  $O$  to table of active objects (DHT), and update  $O$ 's in the objects' table (OHT)
- ④ Lines 16–17:  $O.flag$  is LEAVE so remove the object from DHT. Get the possible cells that  $O$  can move to
- ⑤ Lines 18–25: if the device is undirected, set  $O$  in OHT and add  $O$  to CNHT for the cells in  $sSet$ , else apply the same to CDHT

# Deriving Uncertain Regions for Indoor Moving Objects

For outdoor moving objects [1], **Uncertainty Region**, denoted by  $UR(o, t)$ , is a region such that  $o$  must be in this region at time  $t$ .

In general terms, an object  $o_i$ 's location can be modeled as a random variable with a probability density function  $f_{o_i}(x, y, t)$  that has non-zero values only in  $o_i$ 's uncertainty region  $(o_i, t)$ .

$$\int_{UR(o_i, t)} f_{o_i}(x, y, t) dx dy = 1 \quad (5)$$

# Deriving Uncertain Regions for Indoor Moving Objects

Assume that an *indoor object* has the same probability to be located anywhere inside its uncertainty region:

$$f_{o_i}(x, y, t) = \frac{1}{\text{Area}(UR(o_i, t))}, \quad (x, y) \in UR(o_i, t) \quad (6)$$

- **Active object:** the activation range of the corresponding device.
- **Deterministic object:** the intersection between the object's cell and its *maximum-speed constrained circle*.
- **Nondeterministic object:** the union of the intersection between each cell and the circle.

# PT $k$ NN Query Processing

## Definition (Indoor Probabilistic Threshold $k$ NN Query)

Given a set of indoor moving objects  $O = \{o_1, o_2, \dots, o_n\}$  and a threshold value  $T \in (0, 1]$ , a PT $k$ NN query issued at time  $t$  with query location  $q$  returns a result set

$\mathbb{R} = \{A | A \subseteq O \wedge |A| = k \wedge \text{prob}(A) > T\}$ , where  $\text{prob}(A)$  is the probability that  $A$  contains the  $k$  nearest neighbors of the query location  $q$  at time  $t$ .

when the number of moving objects increases, the number of  $k$ -subsets ( $A$  in Definition 1) in the result set  $\mathbb{R}$  increase exponentially. Specifically, there are  $\binom{n}{k}$  possible  $k$ -subsets for a PT $k$ NN query over  $n$  objects.

# PT $k$ NN Query Processing

Three techniques are proposed to speed up PT $k$ NN query processing:

- ① minimum indoor walking distances between the query location and the (uncertainty regions of) objects are used to prune the objects too far away to be in any possible  $k$ -subset, results in a subset  $O' \subseteq O$ .
- ② for all  $k$ -subsets of  $O'$ , cost-efficient probability estimates are used to prune the  $k$ -subsets whose probabilities definitely are lower than the threshold  $T$ .
- ③ for each remaining  $k$ -subset  $A$ , add  $A$  to  $\mathbb{R}$  only if  $prob(A) > T$ .

# PT $k$ NN Query Processing

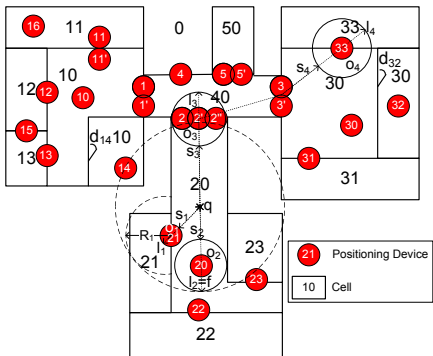

Let  $s_i(l_i)$  be the minimum(maximum) MIWD from  $q$  to the uncertainty region of  $o_i$ :

## 2.3 Probabilistic Threshold k Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space

## PTkNN Query Processing

Let  $s_i(l_i)$  be the minimum(maximum) MIWD from  $q$  to the uncertainty region of  $o_i$ :

$$s_i = \min_{p \in UR(o_i, t)} d_{MIW}(q, p); \quad l_i = \max_{p \in UR(o_i, t)} d_{MIW}(q, p) \quad (7)$$

- $o_1$  is being observed by  $device_{12}$
- $o_2, o_3, o_4$  recently left  $device_{20}, device_{21}, device_{33}$  respectively
- $o_4$ 's MIWD computation should take into account the door connectivity

# PT $k$ NN Query Processing

## Definition (k-bound)

Let  $f$  be the  $k$ th minimal one of all objects'  $l_i$ s. If  $s_i$  of object  $o_i$  is greater than  $f$ , object  $o_i$  has no chance to be in any  $k$ -subset of the result set  $\mathbb{R}$ . This  $f$  value is called the k-bound. [2]

- k-bound can be calculated and updated dynamically during the distance based pruning as soon as  $k$  objects have been seen from  $O$ .
- by taking advantage of indoor space distance definition, the computation cost can be further reduced. E.g., the objects in the same cell can be pruned if one is pruned by the k-bound.

27:              $O' \leftarrow O' \cup DHT[dev]$ ;
28:             Add  $c$  into  $seeds$ ;  $EnheapDoors(H, c)$ ;
29:   if  $|O'| \geq k$  then
30:      $f \leftarrow Bound(O')$ ;

```

---

- ① Lines 1–4: initialization: candidate object set  $O'$ , k-bound  $f$ , cell set  $seeds$  records the examined cells, min-heap  $H \langle \langle d, v \rangle \rangle$  gives priority to doors closer to location  $q$
- ② Lines 5–8: if  $q$  is in  $dev$ 's activation range, active objects in  $dev$  are added to  $O'$ , the nearby objects are added are also added to  $O'$
- ③ Lines 9–13: if not, the covering cell  $c$  is added to set  $seeds$ , add both deterministic and nondeterministic objects to  $O'$
- ④ Lines 14–15: determine the k-bound from the current  $O'$
- ⑤ Lines 17–30: expansion step followed Dijkstra, stops when the entry's distance is too far away, if  $|O'| > k$  then update  $f$  and reduce the candidate set  $O'$

# Probability Threshold Based Pruning

*There can still be  $\binom{|O'|}{k}$  possible  $k$ -subsets in result set  $\mathbb{R}$ .*

# Probability Threshold Based Pruning

*There can still be  $\binom{|O'|}{k}$  possible  $k$ -subsets in result set  $\mathbb{R}$ .*

Given an object  $o_i$ , let  $P_{o_i}(r)$  be the cumulative distribution function that  $o_i$ 's MIWD to the query location  $q$  is  $r$ :

# Probability Threshold Based Pruning

*There can still be  $\binom{|O'|}{k}$  possible  $k$ -subsets in result set  $\mathbb{R}$ .*

Given an object  $o_i$ , let  $P_{o_i}(r)$  be the cumulative distribution function that  $o_i$ 's MIWD to the query location  $q$  is  $r$ :

$$P_{o_i}(r) = Pr(d_{MIW}(q, o_i) \leq r) \quad (8)$$

Let  $A$  be a  $k$ -subset of  $O'$ . The probability  $Prob(A)$  that  $A$  contains the  $k$  nearest neighbors of  $q$  satisfies:

# Probability Threshold Based Pruning

*There can still be  $\binom{|O'|}{k}$  possible  $k$ -subsets in result set  $\mathbb{R}$ .*

Given an object  $o_i$ , let  $P_{o_i}(r)$  be the cumulative distribution function that  $o_i$ 's MIWD to the query location  $q$  is  $r$ :

$$P_{o_i}(r) = \Pr(d_{MIW}(q, o_i) \leq r) \quad (8)$$

Let  $A$  be a  $k$ -subset of  $O'$ . The probability  $\text{Prob}(A)$  that  $A$  contains the  $k$  nearest neighbors of  $q$  satisfies:

$$\text{Prob}(A) \leq \prod_{o_i \in A} P_{o_i}(f) \quad (9)$$

If  $P_{o_i}(f)$  is less than the threshold  $T$ , any  $k$ -subset  $A$  that contains  $o_i$  satisfies:

# Probability Threshold Based Pruning

*There can still be  $\binom{|O'|}{k}$  possible  $k$ -subsets in result set  $\mathbb{R}$ .*

Given an object  $o_i$ , let  $P_{o_i}(r)$  be the cumulative distribution function that  $o_i$ 's MIWD to the query location  $q$  is  $r$ :

$$P_{o_i}(r) = \Pr(d_{MIW}(q, o_i) \leq r) \quad (8)$$

Let  $A$  be a  $k$ -subset of  $O'$ . The probability  $\text{Prob}(A)$  that  $A$  contains the  $k$  nearest neighbors of  $q$  satisfies:

$$\text{Prob}(A) \leq \prod_{o_i \in A} P_{o_i}(f) \quad (9)$$

If  $P_{o_i}(f)$  is less than the threshold  $T$ , any  $k$ -subset  $A$  that contains  $o_i$  satisfies:

$$\text{Prob}(A) \leq \prod_{o_i \in A} P_{o_i}(f) \leq P_{o_i}(f) \leq T \quad (10)$$

Therefore, if  $P_{o_i}(f) \leq T$ ,  $o_i$  can be safely pruned from the candidate.

# Probability Evaluation

*After probability threshold pruning, each  $k$ -subset  $A$  in  $\mathbb{R}$  may have their  $Prob(A)$  greater than  $T$ .*

Define  $Prob(A)$  as:

# Probability Evaluation

*After probability threshold pruning, each  $k$ -subset  $A$  in  $\mathbb{R}$  may have their  $Prob(A)$  greater than  $T$ .*

Define  $Prob(A)$  as:

$$Prob(A) = \sum_{o_z \in A} \int_0^{+\infty} p_{o_z}(r) \prod_{o_i \in A \setminus \{o_z\}} P_{o_i}(r) \prod_{o_j \in O' \setminus A} (1 - P_{o_j}(r)) dr \quad (11)$$

## 2.3 Probabilistic Threshold k Nearest Neighbor Queries over Moving Objects in Symbolic Indoor Space

## Probability Evaluation

*After probability threshold pruning, each  $k$ -subset  $A$  in  $\mathbb{R}$  may have their  $Prob(A)$  greater than  $T$ .*

Define  $Prob(A)$  as:

$$Prob(A) = \sum_{o_z \in A} \int_0^{+\infty} p_{o_z}(r) \prod_{o_i \in A \setminus \{o_z\}} P_{o_i}(r) \prod_{o_j \in O' \setminus A} (1 - P_{o_j}(r)) dr \quad (11)$$

	$sl[0]=s_1$	$sl[1]=s_2$	$sl[2]=l_1$	$sl[3]=s_3$	$sl[4]=l_2$
$o_1$	0.2	1	1	1	
$o_2$	0	0.3	0.7	1	
$o_3$	0	0	0	0.5	
	$PA_1$	$PA_2$	$PA_3$	$PA_4$	

- $o_z$  is the  $k$ -th nearest neighbor of  $q$ .
- to evaluate the probabilities efficiently, a partition based approximate evaluation method is used.
- let an array  $sl$  records all the minimum distances  $s_i$  in  $O'$  and the maximum distances  $l_i$  that satisfy  $l_i \leq f$ .
- $sl$  should have  $g = |O'| + k$  elements, sort it in ascending order.

# Research Directions

- Analyzing historical trajectory data may discover associations among object movements, which can be used to design more efficient group pruning in processing a  $PT^kNN$  query
- Regarding the uncertainty model of indoor moving objects, it is also interesting to conduct probabilistic analysis on other kinds of object distribution.
